POSITION STATEMENT

The Effect of Environmental Toxins on Reproductive and Developmental Health

The American College of Nurse-Midwives (ACNM) affirms that midwives and other reproductive health care professionals have ethical and professional responsibilities to address risks of environmental contamination through the following actions:

- Increase individual awareness of the presence and effects of various environmental contaminants.
- Provide appropriate education and interventions for adults or newborns exposed to environmental toxins.
- Encourage policy and program development and continuing research to promote a cleaner, safer environment.

Background on Environmental Toxins in the United States

Researchers increasingly demonstrate links between environmental contaminants and human diseases. Toxic chemicals are encountered daily through water; air; food; personal care products; and home, work, and community environments. Currently, the majority of the more than 84,000 chemicals produced or used in the US have not undergone comprehensive testing for human toxicity. The Centers for Disease Control and Prevention tracks the bioaccumulation of chemicals in humans and has identified hundreds of chemicals of concern in blood and urine samples of US residents across all demographics. All people are exposed to fetotoxic chemicals. Many toxic chemicals cross the placenta, and some accumulate at greater concentrations in the fetus than in the adult. Hundreds of exogenous chemicals have been identified in samples of newborn cord blood.

Foreign chemicals compromise the delicate processes of reproduction and fetal development. Exposures have been linked with irreversible, life-long, and even multigenerational effects such as birth defects, developmental delays, and adult-onset illnesses. For example, industrial chemicals known as endocrine disruptors disrupt hormone function and are found in industrial air pollution; food contaminated by pesticides and heavy metals; and some plastics, cosmetics, and paper products. Endocrine disruptors are linked to adverse health outcomes such as altered puberty onset, infertility, aneuploidy, miscarriage, preeclampsia, fetal growth restriction, preterm delivery, menstrual irregularities, polycystic ovary syndrome, uterine fibroids,
endometriosis, shortened lactation, breast cancer, early menopause, thyroid dysfunction, obesity, diabetes, and cardiovascular diseases.\textsuperscript{10,11} Contrary to prior belief, safe, low levels do not exist for many chemicals. Just as natural hormones are active at extremely low concentrations and initiate various physiologic functions based on level of exposure, some endocrine disruptors have been found to be more active and dangerous at low levels than at high levels.\textsuperscript{12}

ACNM joins numerous, prominent organizations that have spoken out on this issue and recognizes the need for increased efforts from ACNM members and other responsible parties to address the mounting problem of environmental pollution.\textsuperscript{13-20}

**Patient Education and Interventions**

Exposure to many chemicals is preventable. Midwives are required to possess knowledge about environmental hazards encountered during preconception, pregnancy, and the postpartum period. They are ideally positioned to prevent or limit toxic exposure in adults, fetuses, and infants.\textsuperscript{21,22} Prior efforts to reduce exposures to alcohol, tobacco, mercury, and lead have been successful.

Midwives can now play a pivotal role in limiting peoples’ contact with other well-documented hazards, including air pollution, bisphenol A, disinfection byproducts, pesticides, petroleum products, phthalates, solvents, chlorinated hydrocarbons, and metals.\textsuperscript{23}

While all adults and children are exposed to environmental toxins to some degree, midwives can identify populations that are exposed to contamination at greater-than-average rates as well as those that are most susceptible to exposure. Risk factors include low socioeconomic status, poor housing quality, occupational exposures such as agricultural pesticides and products used by nail salon workers, poor health, poor nutrition, and psychosocial stressors.\textsuperscript{24,25}

Many local and national resources exist to assist midwives in addressing this issue with the families they serve. To promote change, midwives may include environmental history assessment as a routine part of primary care,\textsuperscript{26} educate families to increase their awareness and encourage healthy behavioral changes,\textsuperscript{27,28} and enhance their own professional knowledge on this issue.\textsuperscript{29,30}

**Recommendations for Policy and Research to Promote a Cleaner, Safer Environment**

Many environmental exposures are beyond the control of the individual. Institutional and political changes are critical to prevent harmful chemical exposures. ACNM recognizes the certified nurse-midwife (CNM)/certified midwife (CM) as a member of a larger community working toward a cleaner environment. Midwives can act as change agents for environmental
protection and can be instrumental in influencing regulations where they live. They can also influence policies in the hospitals, birth centers, and homes where they work.\textsuperscript{24} The fact that environmental toxins are harmful to adults and children presents a challenge and an opportunity for change.\textsuperscript{31}

ACNM acknowledges the need for legislative and regulatory bodies to identify and uphold restrictions and bans on known and suspected toxic chemicals. ACNM also supports increasingly robust research and investigation regarding causal relationships between toxic chemicals and disease. Further, ACNM supports industry and regulatory efforts for more socially responsible chemical use and increasing efforts to assist populations already harmed by exposure to toxic chemicals. In cases where research has not fully clarified the causal relationships between chemicals and disease, ACNM supports leading scientists in advocating for precautionary principles to be employed.\textsuperscript{17}
